However the query can be rewritten as select * from table1, table2, table3 where... inner join (select column from table1) t1 on table1.column = t1.column inner join (select column from table2) t2 on table2.column = t2.column inner join (select column from table3) t3 on table3.column = t3.column However I don't know how to generalize this into a stored procedure that can accept various tables to join on. I don't want to write each select statement. I don't know if SQL 2000 has a stored procedure/index support for this. The indexing I'm after is the part of the (calculated) column being used to join against, e.g. column "metrics.some_table" in this case. The query is performed on a subset of data - sometimes the data is so huge that the sub-queries are even slow with the full table, so a full re-write into a stored procedure is out of the question. Any ideas? A: You can do this with nested loop joins. For example, if there are columns t1.a and t2.a, and you want to join t1.x to t2.x for each row of t1, then you can do: select * from table1 t1 inner join table2 t2 on t1.a = t2.a inner join table1 t1_alias on t1_alias. f678ea9f9e
